Introduction

The design of a functional coating on a substrate usually requires **different layers**, each of them having a **specific role**. So, the development of **innovative coatings** with **multifunctional properties** is very challenging. **Self-stratification** can be an alternative as it is an eco-efficient process allowing the formation, in only **one application**, of a **multi-layer film**.

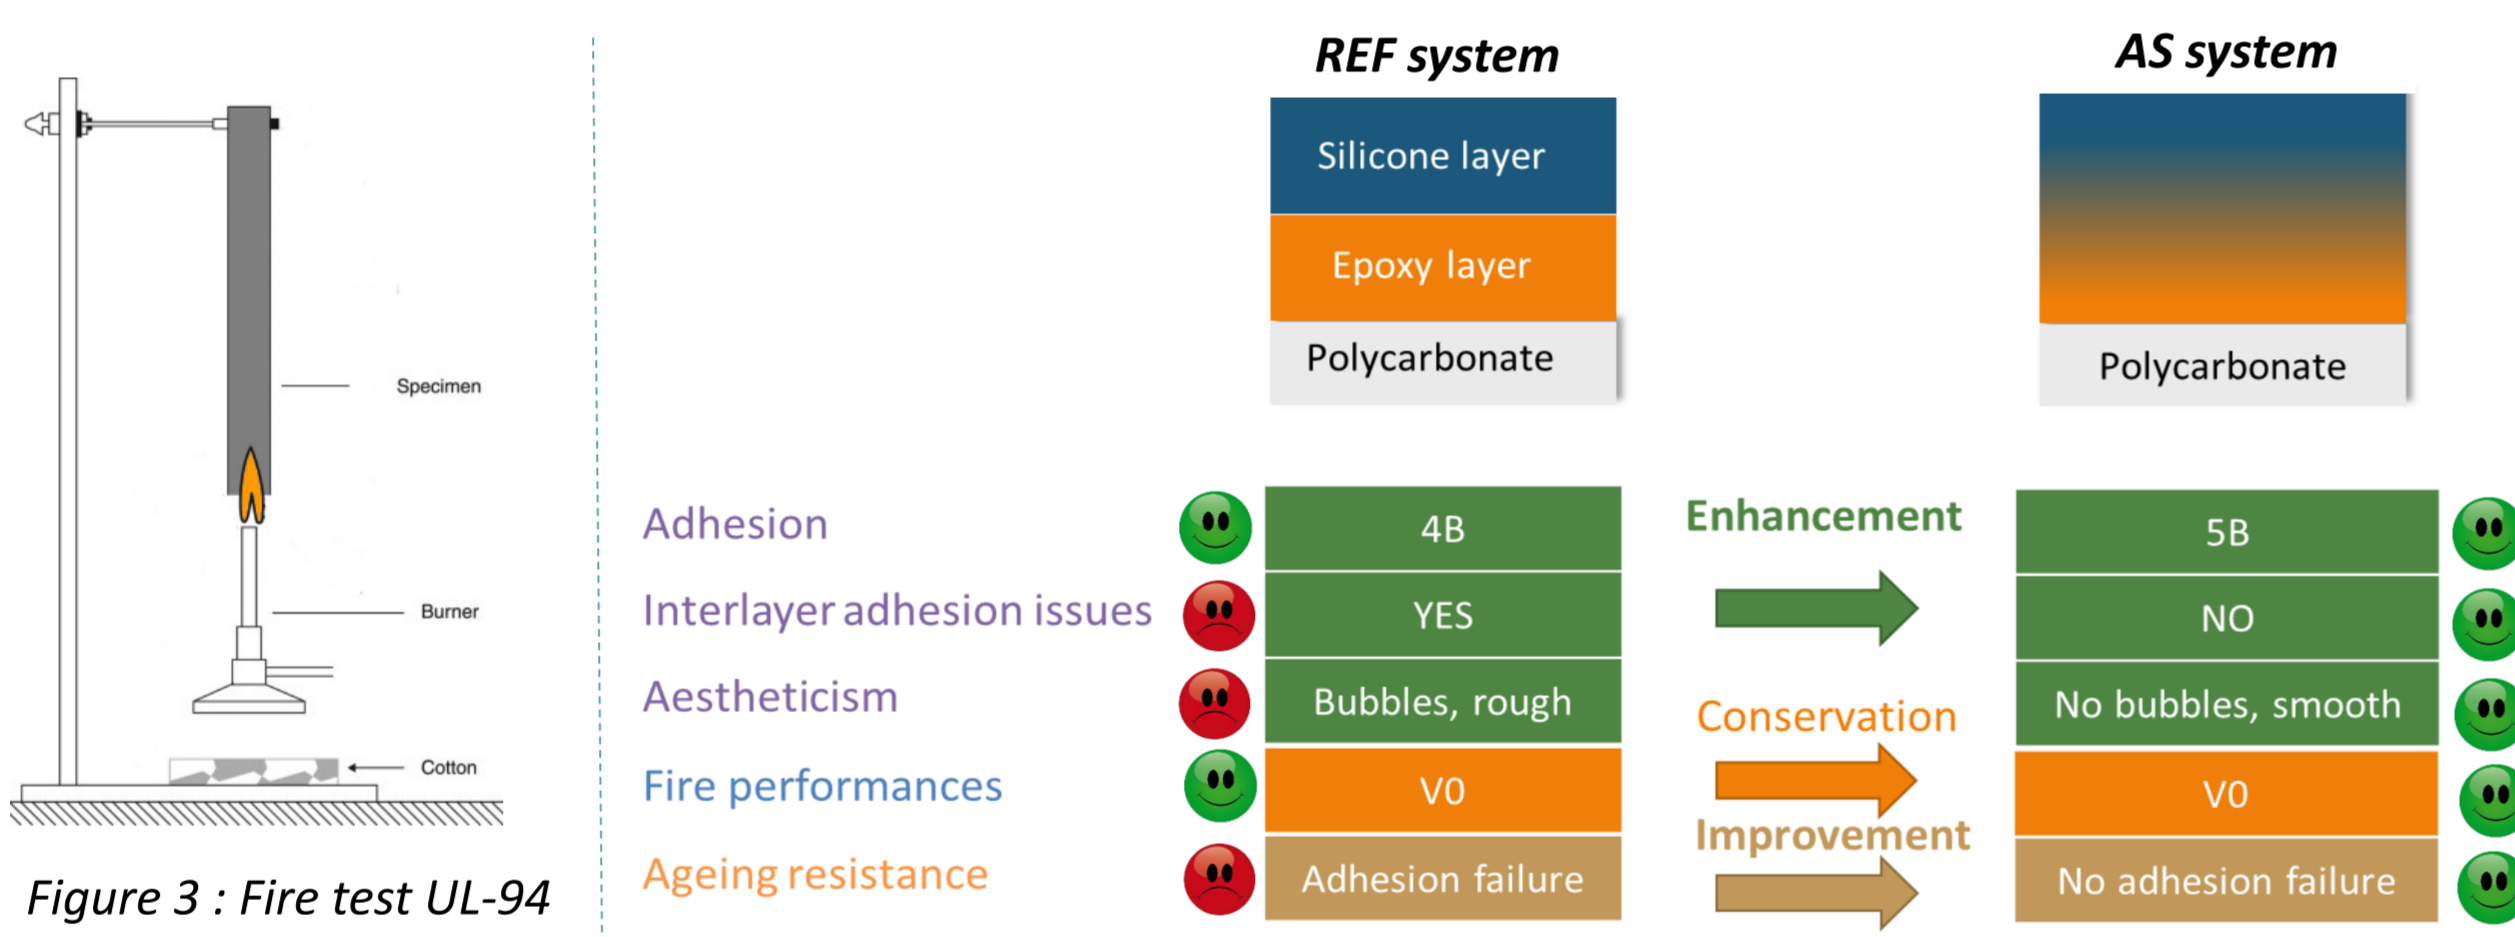

Coatings properties

The **reference system (REF)** is made of **two distinct layers** : epoxy resin as bottom layer and silicon resin as upper layer. In the **self-stratifying coating (AS)**, silicone and iron oxide migrate to the upper layer (Figure 2).

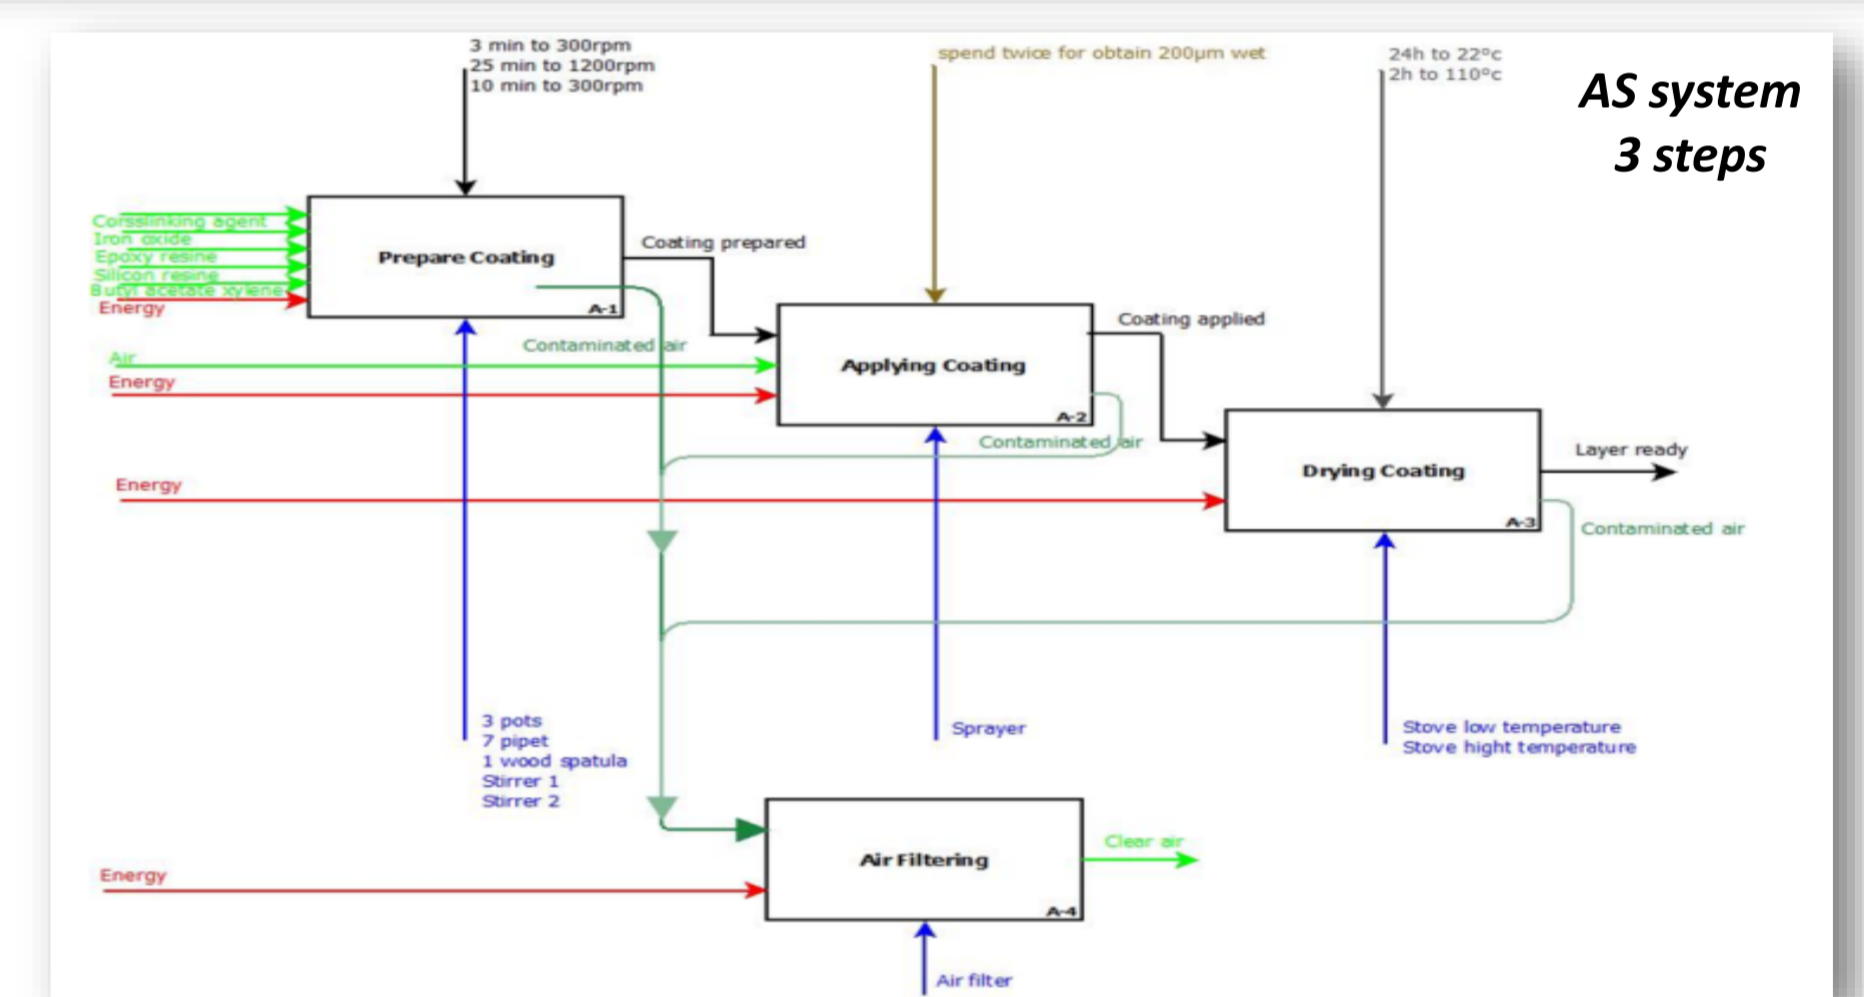

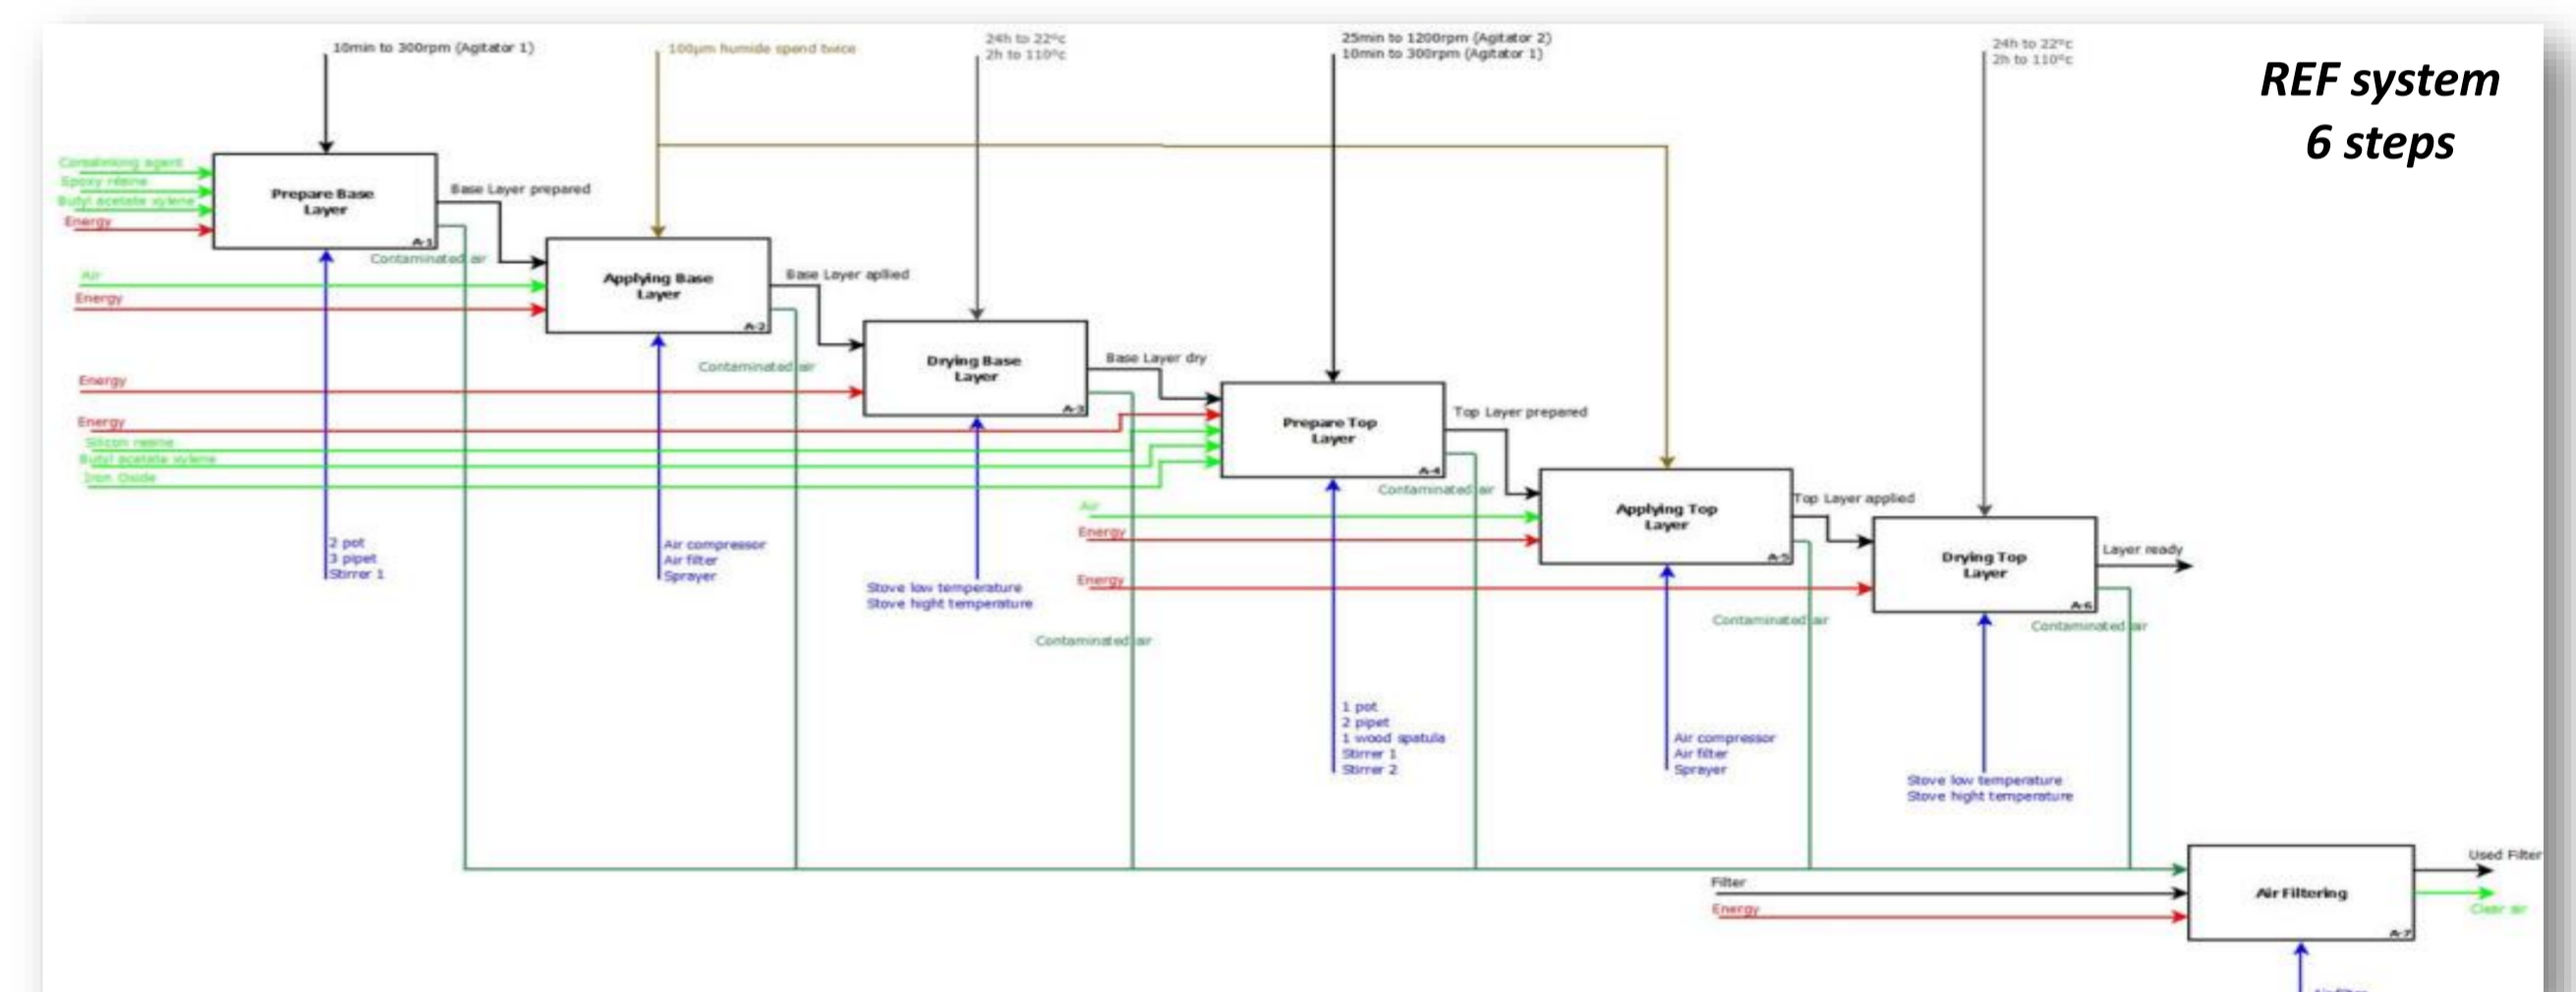

The samples were tested to a fire test UL-94 (Figure 3). It evaluate the tendency of a material to **extinguish** or to **spread the flame** after **ignition** of a material. Other characteristics have been evaluated in order to compare both systems (Figure 4). The **global performances of the AS system** appear **more interesting** than those of the REF system.

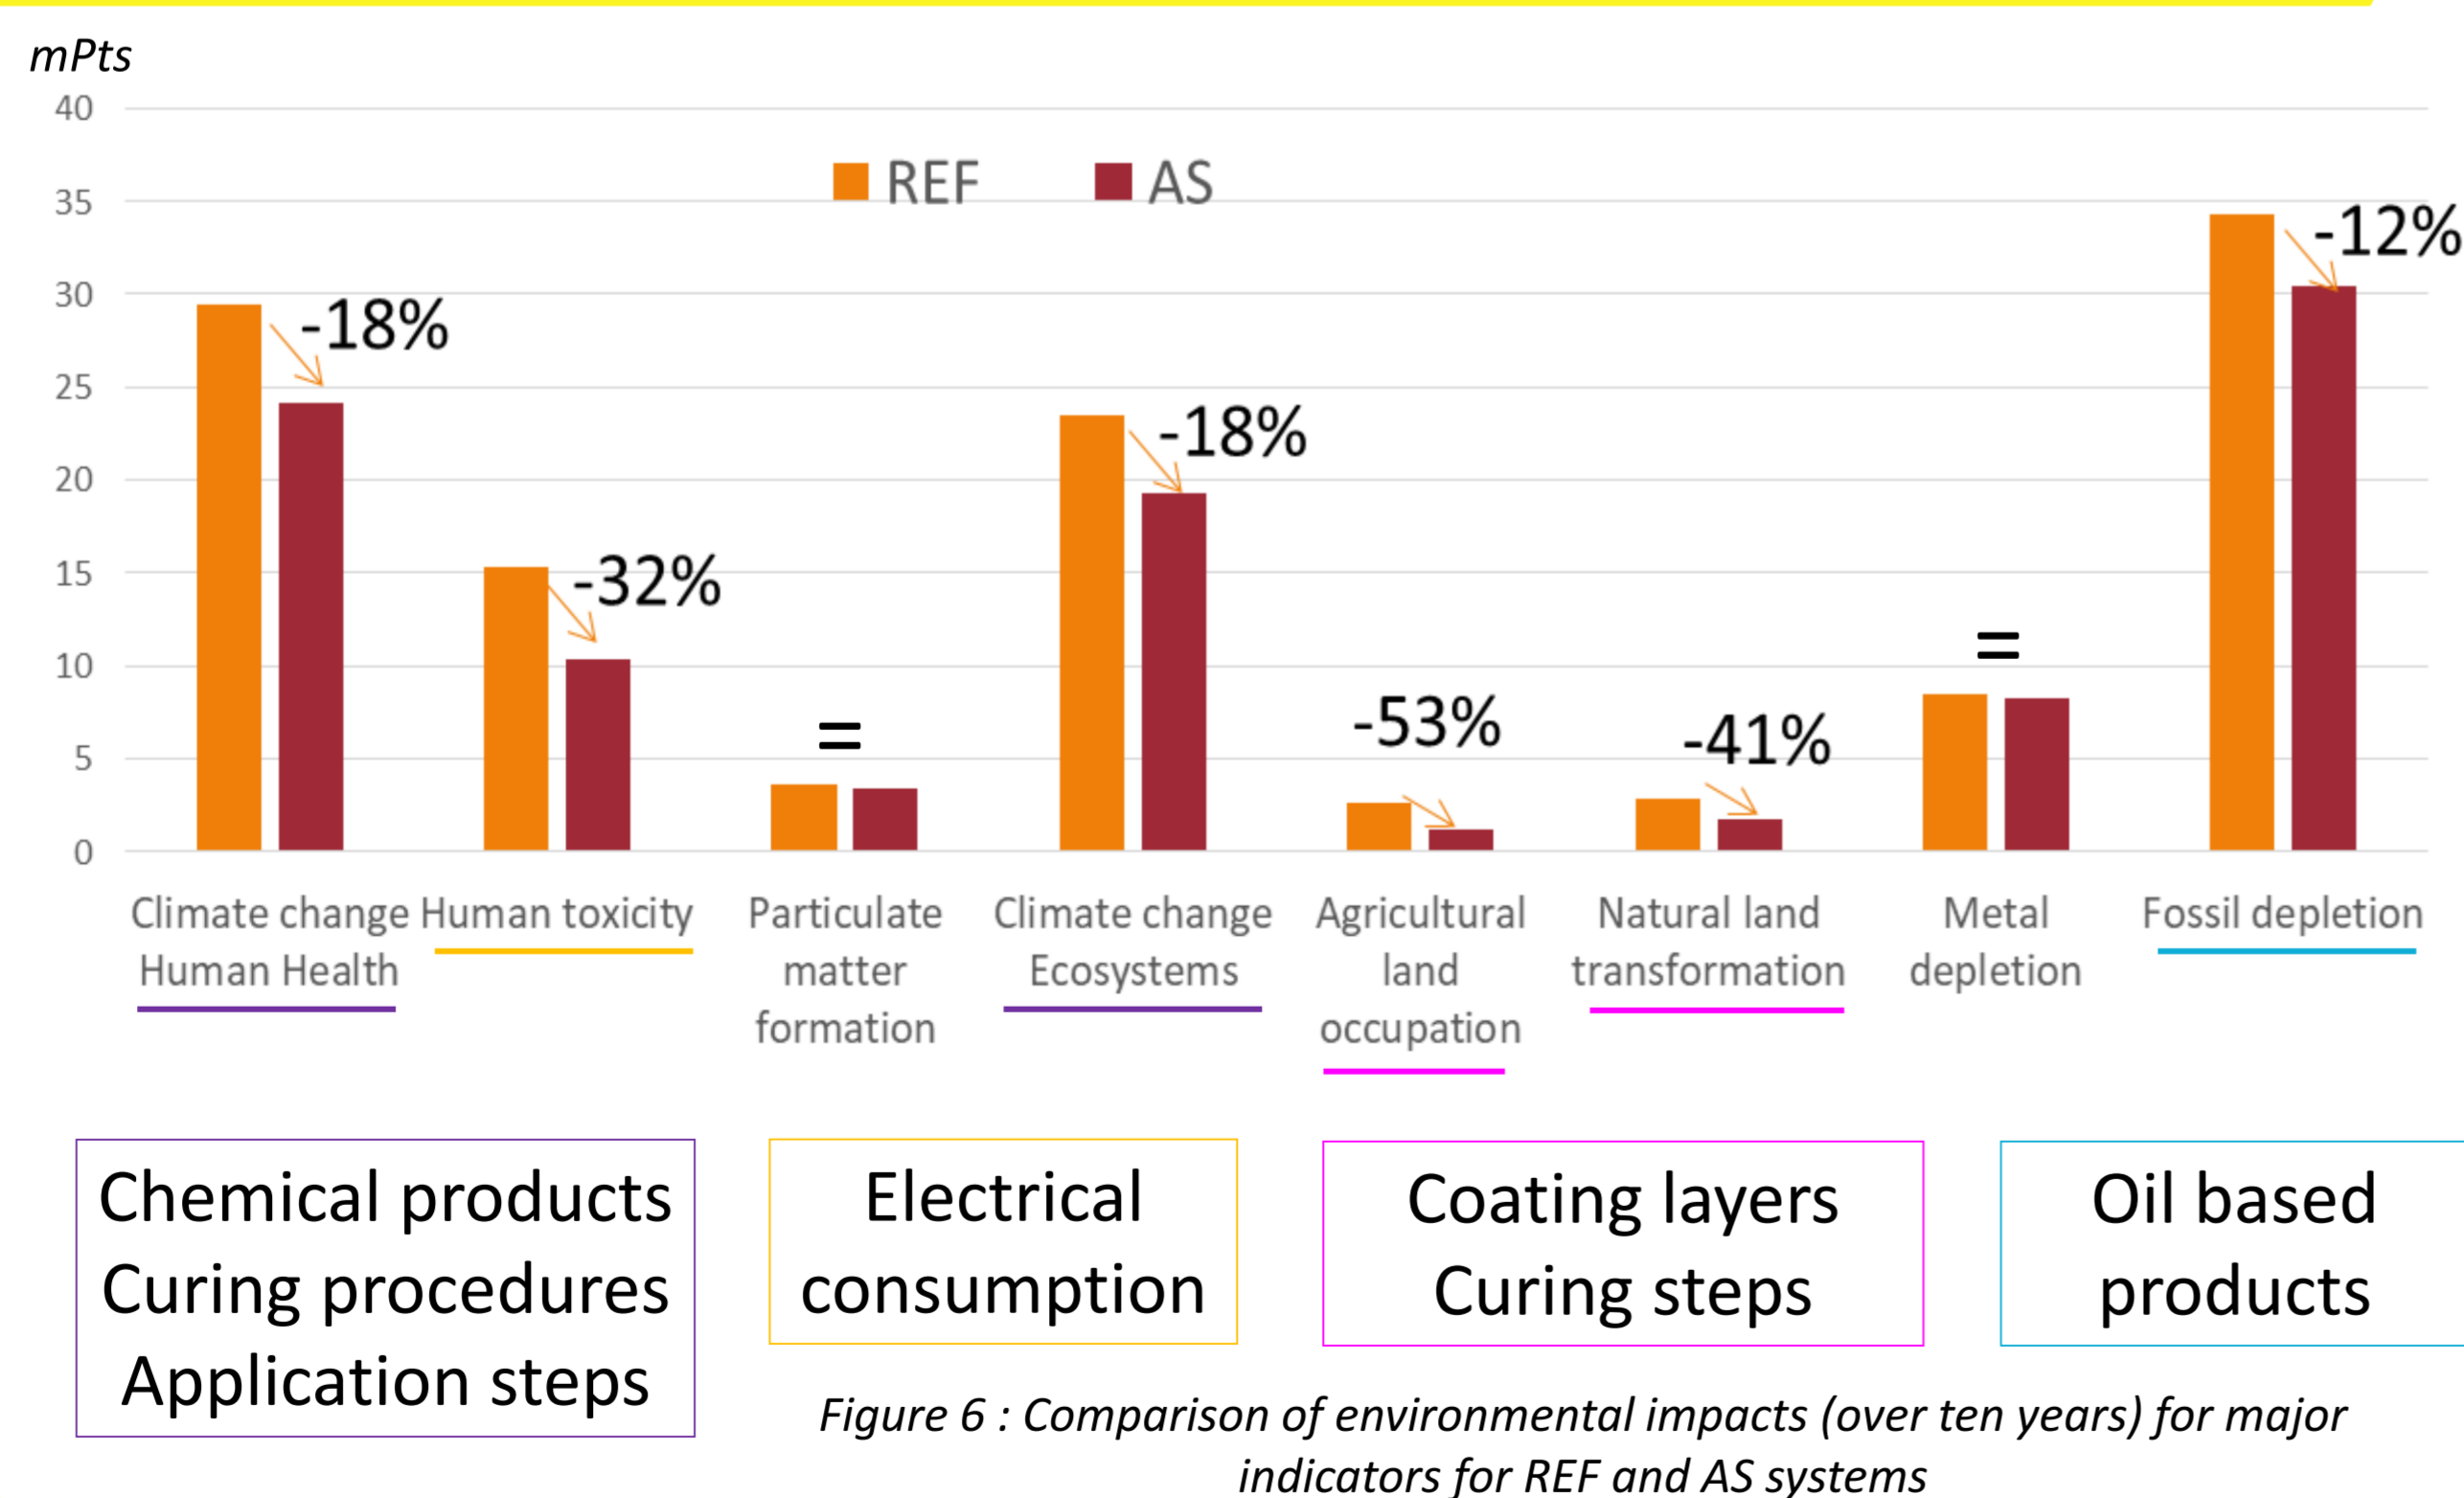

Functional analysis

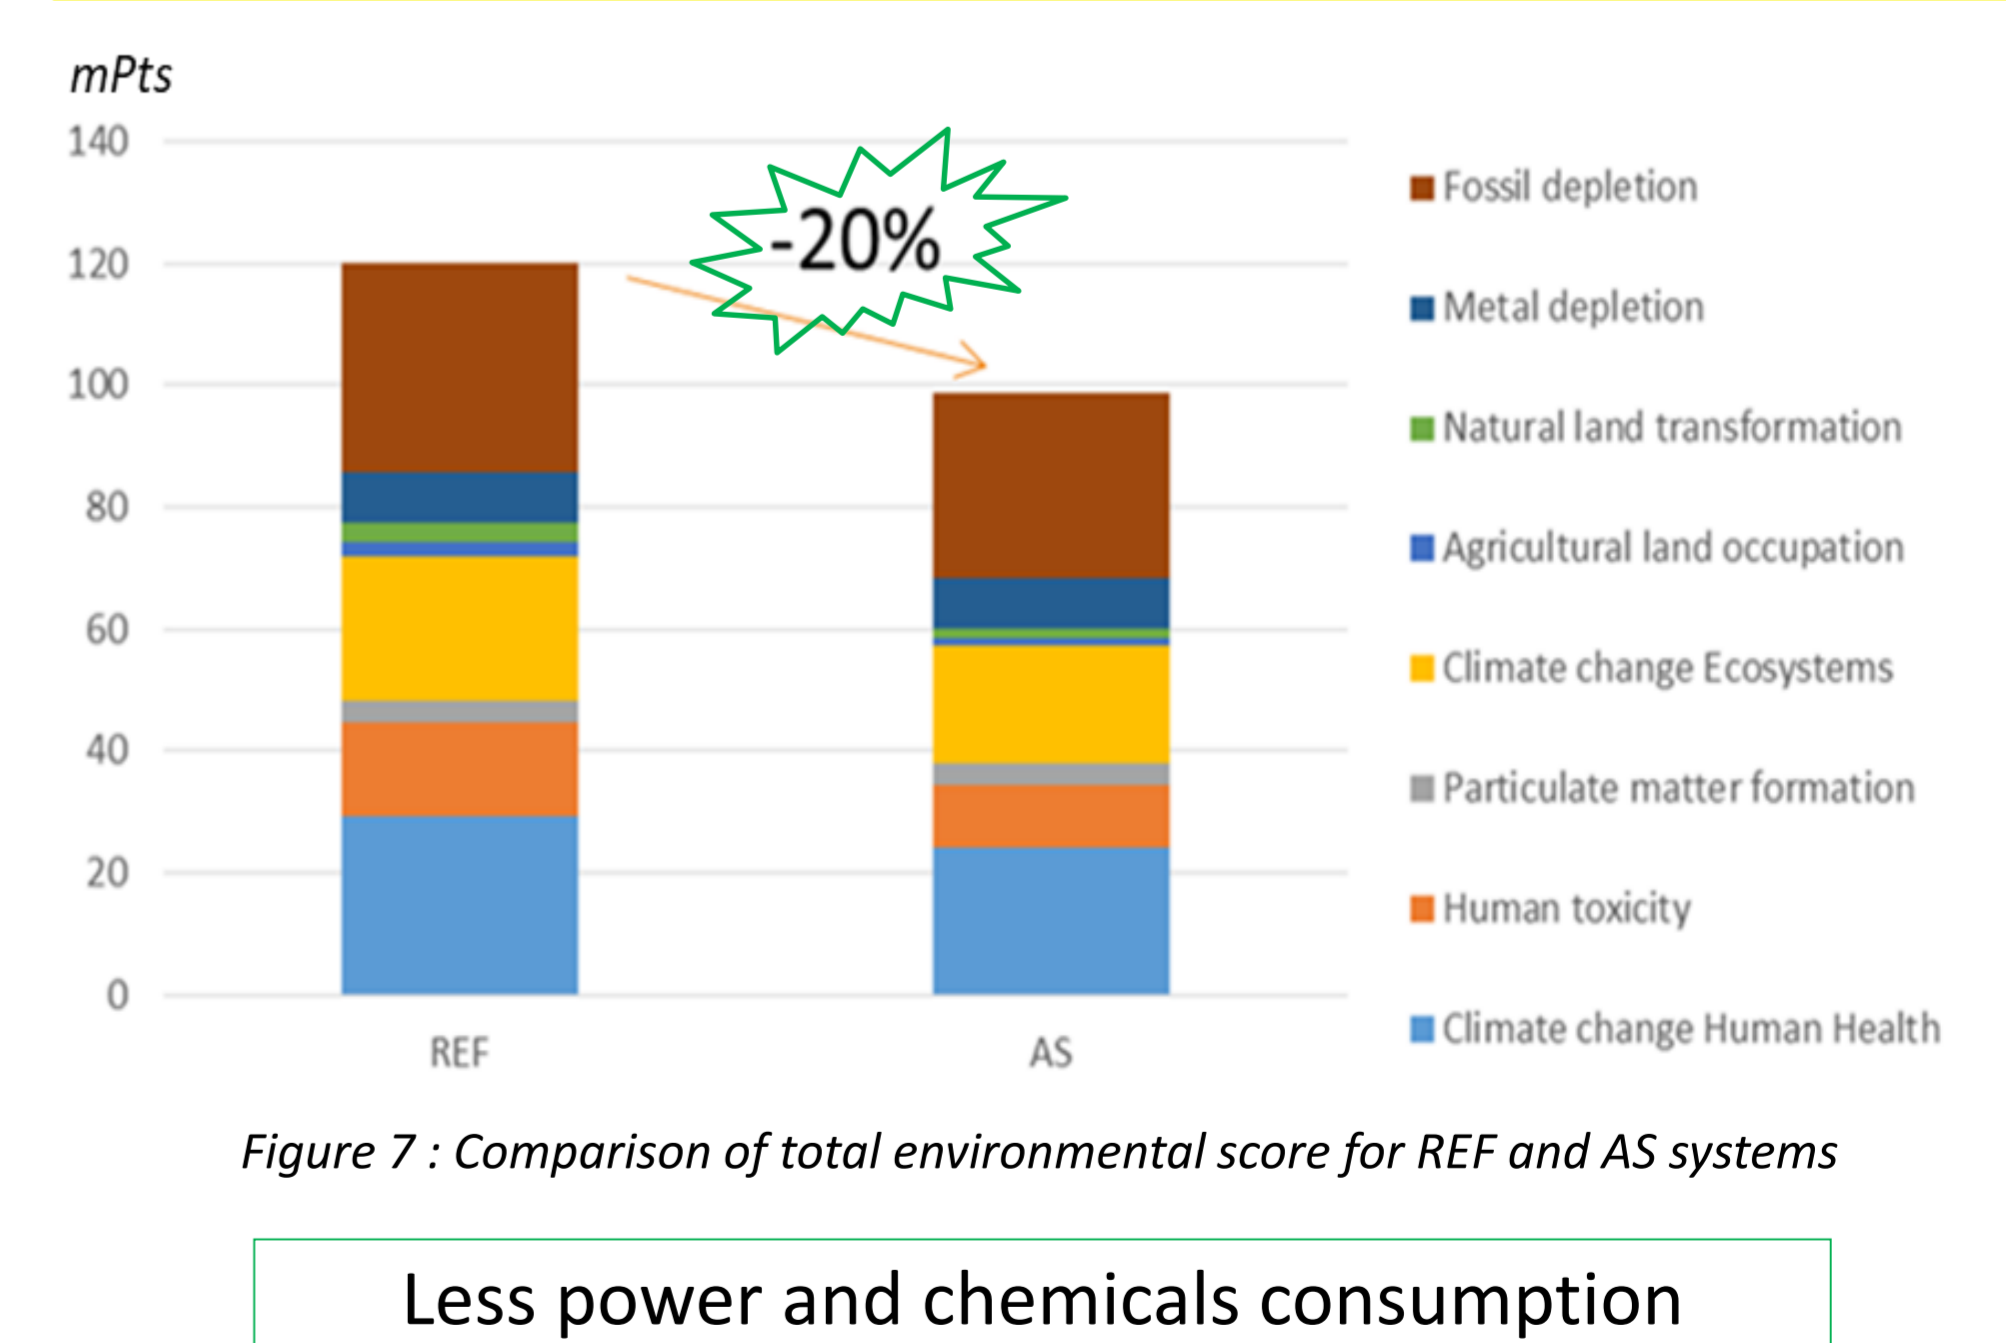

LCA was carried out on **two lab scale coating processes**. **Functional unit (FU)** : "Deposit on a 100cm² polycarbonate plate a coating allowing reaching a V0 rating at UL94"
Calculation method : Recipe E 1,12 (Europe)

Results of LCA

Conclusion

The next step of this work is to carry out the same study on a **flame retardant self-stratifying coating based on eco-friendly products** (bio-based epoxy resin, green solvent ...) to see the influence on the global environmental impact.
