^a reaction at 81°C for 7 days in 20 mL or 60 mL of cyclohexane (respectively 0.1 and 0.033 mol/L vs diol), diol-diamide/diester (2 mmol/2 mmol), Novozyme 435 (10 % weight vs. monomers), Dean Stark apparatus with molecular sieves (replaced every 48h)

^b SEC in chloroform at 25°C (polystyrene standards), M_n and D_M for main peak

^c main peak and secondary peaks distributions represent high M_n oligomers and small oligomers (M_n = 300-800 g/mol, D_M = 1-1.3), respectively.

^d % by weight main peak = [area of main peak / (area of main peak + area of secondary peaks)] *100

^e corrected yield = yield x main peak wt(%) / 100

^e T_g , T_c (crystallization) and T_m (melting) determined by DSC on the second heating step.

^f TGA temperatures at which 3 % of the mass was lost

^g TGA temperatures for start of second degradation (inflection point of weight = f(T))

The polycondensation reaction gave higher corrected yield and higher M_n in lower volumes of solvent except for x=2 (entries 11-11')
